monitoring system consistent with the objectives of	,
the program. If the system is intended to provide	
information on presence or absence of a fish, then	
diagnostics and tests need to be collected during the	
course of the study to ascertain the reliability of the	
data. Simply knowing the receivers are on is not	
sufficient. For example, if a fish is not detected in the	
array, qa/qc procedures need to be able to establish	
that as a true, not false negative. Similarly, QA/QC	
approaches are needed to establish the accuracy and	
precision of location data in the high resolution	
	as need be.  Section 2.4. To maximize the potential for the highresolution array to be useful, these areas should be prioritized for fish collection.  Section 3.1. I recommend adding Dan Isermann, Univ WI Stevens Point, as the "expert assistance and review". He is the nation's foremost expert on SMB tracking in Large Rivers using the Vemco technologies.  2.6/4.6.1. SMB are believed to move to spawning and wintering areas. For the purposes of this study, it would not be useful to collect "in-transit" fish as they cannot be reasonably expected to reside within the tracking area. Fish should be collected post-spawning after they have established summer residence. Local fisheries experts would be best suited to inform specific dates, but pre- or during-spawn sampling would not provide an appropriate population sample for the purposes of establishing the home range of resident SMB.  The receiver deployment array is relatively sparse, increasing the chance that fish will not be "heard" either as it resides in the array or transits beyond the array. The lack of a signal increases the ambiguity of outcome (is a fish gone, or just not heard). How will the system indicate directionality and distance from the gates (has a fish transited from the array and is not heard)? Different interpretations will provide fundamentally different determinations on residency.  Missing. Information needs to be provided on a QA/QC plan to document the performance of the monitoring system consistent with the objectives of the program. If the system is intended to provide information on presence or absence of a fish, then diagnostics and tests need to be collected during the course of the study to ascertain the reliability of the data. Simply knowing the receivers are on is not sufficient. For example, if a fish is not detected in the array, qa/qc procedures need to be able to establish that as a true, not false negative. Similarly, QA/QC
